Savage River State Forest Forest Inventory Summary

File Date: **2014-04-18**

This is a summary of the Savage River State Forest (SRSF) forest stand inventory that has been collected and entered into the computer system. The data represents all data collected before last summer season (2013) and part of the 2013 season. The data is sorted by relative density and then site index. The trees listed are the dominant species across the forest.

It has been suspected that the data will suggest that SRSF may have overstocked stands and, the data thus far indicates that is correct. According to the preliminary data presented, 35 % (or 8,298 acres) are overstocked (using a relative density of 90 as the threshold). However, this is a conservative estimate because we did remove stands that have been treated in the last few years. Other practical factors contribute to the overstocking now and into the future include: steep slopes, access problems and ESAs. These factors limit the amount of silvicultural work that can be done across the forest system. As a result, this inventory will be adjusted to consider these factors.

To accommodate these findings, SRSF will address the overstocking problem by adjusting annual work plans and prioritizing work in those stands that have the highest relative density. In Fiscal Year 2016 and beyond, SRSF will target 24 treatments per year or roughly 408 acres/year (assuming the average stand is 17 acres in area). More than 24 stands will be examined in order to find 24 stands that work can be done in (again the practical limitations of slope, access and ESAs).

The result will be that SRSF will be addressing the worst of the overstocked stands first.

- treating 24 stands or roughly 408 acres per year and thereby reduce the current overstocking level in 20 years.
